5. Worksheet: Alpha Diversity

Dustin Brewer; Z620: Quantitative Biodiversity, Indiana University 21 January, 2019

OVERVIEW

In this exercise, we will explore aspects of local or site-specific diversity, also known as alpha (α) diversity. First we will quantify two of the fundamental components of (α) diversity: **richness** and **evenness**. From there, we will then discuss ways to integrate richness and evenness, which will include univariate metrics of diversity along with an investigation of the **species abundance distribution (SAD)**.

Directions:

- 1. In the Markdown version of this document in your cloned repo, change "Student Name" on line 3 (above) to your name.
- 2. Complete as much of the worksheet as possible during class.
- 3. Use the handout as a guide; it contains a more complete description of data sets along with the proper scripting needed to carry out the exercise.
- 4. Answer questions in the worksheet. Space for your answer is provided in this document and indicated by the ">" character. If you need a second paragraph be sure to start the first line with ">". You should notice that the answer is highlighted in green by RStudio (color may vary if you changed the editor theme).
- 5. Before you leave the classroom, **push** this file to your GitHub repo.
- 6. For the assignment portion of the worksheet, follow the directions at the bottom of this file.
- 7. When you are done, **Knit** the text and code into a PDF file.
- 8. After Knitting, submit the completed exercise by creating a **pull request** via GitHub. Your pull request should include this file AlphaDiversity_Worskheet.Rmd and the PDF output of Knitr (AlphaDiversity_Worskheet.pdf).

1) R SETUP

In the R code chunk below, please provide the code to: 1) Clear your R environment, 2) Print your current working directory, 3) Set your working directory to your 5.AlphaDiversity folder, and 4) Load the vegan R package (be sure to install first if you haven't already).

```
rm(list=ls())
getwd()
```

[1] "C:/Users/dusti/GitHub/QB2019 Brewer/2.Worksheets/5.AlphaDiversity"

```
setwd("C:/Users/dusti/GitHub/QB2019_Brewer/2.Worksheets/5.AlphaDiversity")
install.packages("vegan", repos = "http://cran.us.r-project.org")
```

```
## Installing package into 'C:/Users/dusti/Documents/R/win-library/3.4'
## (as 'lib' is unspecified)
```

```
## package 'vegan' successfully unpacked and MD5 sums checked
##
## The downloaded binary packages are in
## C:\Users\dusti\AppData\Local\Temp\Rtmp2xkFLW\downloaded_packages

library("vegan")

## Warning: package 'vegan' was built under R version 3.4.4

## Loading required package: permute

## Warning: package 'permute' was built under R version 3.4.4

## Loading required package: lattice

## This is vegan 2.5-3
```

2) LOADING DATA

In the R code chunk below, do the following: 1) Load the BCI dataset, and 2) Display the structure of the dataset (if the structure is long, use the max.level = 0 argument to show the basic information).

```
data(BCI)
BCI
```

3) SPECIES RICHNESS

\$ Eugenia.galalonensis

Species richness (S) refers to the number of species in a system or the number of species observed in a sample.

Observed richness

In the R code chunk below, do the following:

- 1. Write a function called S.obs to calculate observed richness
- 2. Use your function to determine the number of species in site1 of the BCI data set, and
- 3. Compare the output of your function to the output of the specnumber() function in vegan.

```
S.obs <- function(x = ""){
   rowSums(x > 0) * 1
}
```

BCI

S.obs(site1)
```

93

```
specnumber(BCI[1,])

## 1
## 93

specnumber(BCI[4,])

## 4
## 94
```

Question 1: Does specnumber() from vegan return the same value for observed richness in site1 as our function S.obs? What is the species richness of the first four sites (i.e., rows) of the BCI matrix?

Answer 1: Yes, specnumber() and our function S.obs() return the same value for observed richness, 93. For the 1st four sites, the species richness is 94.

Coverage: How well did you sample your site?

In the R code chunk below, do the following:

- 1. Write a function to calculate Good's Coverage, and
- 2. Use that function to calculate coverage for all sites in the BCI matrix.

```
C <- function(x = ""){
  1 - (rowSums(x == 1) / rowSums(x))
}</pre>
C(BCI[,])
```

```

Question 2: Answer the following questions about coverage:

a. What is the range of values that can be generated by Good's Coverage?

- b. What would we conclude from Good's Coverage if n_i equaled N?
- c. What portion of taxa in site1 was represented by singletons?
- d. Make some observations about coverage at the BCI plots.

Answer 2a: 0 to 1

Answer 2b: My impression is that all of the observations would be singletons, and so coverage wouldn't be good.

Answer 2c: Only about 7% were represented by singltons

Answer 2d: Overall, coverage seems quite good. The smallest proportion is 0.88, and most are 0.9 or above.

Estimated richness

In the R code chunk below, do the following:

- 1. Load the microbial dataset (located in the 5.AlphaDiversity/data folder),
- 2. Transform and transpose the data as needed (see handout),
- 3. Create a new vector (soilbac1) by indexing the bacterial OTU abundances of any site in the dataset,
- 4. Calculate the observed richness at that particular site, and
- 5. Calculate coverage of that site

```
soilbac <- read.table("data/soilbac.txt", sep = "\t", header = TRUE, row.names = 1)
soilbac</pre>
```

Question 3: Answer the following questions about the soil bacterial dataset.

- a. How many sequences did we recover from the sample soilbac1, i.e. N?
- b. What is the observed richness of soilbac1?
- c. How does coverage compare between the BCI sample (site1) and the KBS sample (soilbac1)?

Answer 3a: 13,310

Answer 3b: 1074

T1_3

Answer 3c: Coverage was less for the KBS sample than the BCI sample.

Richness estimators

##

 $T1_1$

2628.514

- 1. Write a function to calculate **Chao1**,
- 2. Write a function to calculate **Chao2**,
- 3. Write a function to calculate ACE, and
- 4. Use these functions to estimate richness at site1 and soilbac1.

```
Chao1 <- function(x = ""){</pre>
  S.obs(x) + (sum(x == 1)^2) / (2*sum(x == 2))
}
Chao2 <- function(site = "", SbyS = ""){</pre>
  SbyS = as.data.frame(SbyS)
  x = SbyS[site, ]
  SbyS.pa <- (SbyS > 0) * 1
  Q1 = sum(colSums(SbyS.pa) == 1)
  Q2 = sum(colSums(SbyS.pa) == 2)
  Chao2 = S.obs(x) + (Q1^2) / (2*Q2)
  return(Chao2)
ACE <- function(x = "", thresh = 10){
  x \leftarrow x[x>0]
  S.abund <- length(which(x > thresh))
  S.rare <- length(which(x <= thresh))</pre>
  singlt <- length(which(x == 1))</pre>
  N.rare <- sum(x[which(x <= thresh)])</pre>
  C.ace <- 1 - (singlt / N.rare)</pre>
  i <- c(1:thresh)</pre>
  count <- function(i, y){</pre>
    length(y[y == i])
  a.1 <- sapply(i, count, x)</pre>
  f.1 \leftarrow (i * (i - 1)) * a.1
  G.ace <- (S.rare/C.ace)*(sum(f.1)/(N.rare*(N.rare-1)))</pre>
  S.ace <- S.abund + (S.rare/C.ace) + (singlt/C.ace) * max(G.ace,0)
  return(S.ace)
}
Chao1(site1)
##
           1
## 119.6944
Chao1(soilbac1)
```

```
ACE(site1)

## [1] 159.3404

## [1] 4465.983

Chao2(1, BCI)

## 1
## 104.6053

Chao2(1, soilbac.t)

## T1_1
## 21055.39
```

Question 4: What is the difference between ACE and the Chao estimators? Do the estimators give consistent results? Which one would you choose to use and why?

Answer 4: Ace and Chao estimators differ in that the ACE estimator utilizes a threshold for rare species as less than 10, which more broadly defines a rare species (compared to singletons and doubletons of the chao estimators). All of the estimators produced similar estimates for the BCI dataset, though for the soilbac data set the Chao2 estimator produced a higher estimate for richness than the other estimators (>20,000 vs 5000). I'm guessing this is because the Chao2 considered multiple sites and there are many more bacteria species than tree species. I'm not sure what estimator I should use, but my impression is that it may depend on the situation and sample size (perhaps the threshold of 10 is inappropriate in some situations (use Chao1 or 2)? perhaps I want to measure richness at more than one site (use Chao2)?

Rarefaction

In the R code chunk below, please do the following:

- 1. Calculate observed richness for all samples in soilbac,
- 2. Determine the size of the smallest sample,
- 3. Use the rarefy() function to rarefy each sample to this level,

1074 1302 1174 1416 1406 1143 1806 1151 924 1122 851

- 4. Plot the rarefaction results, and
- 5. Add the 1:1 line and label.

```
soilbac.S <- S.obs(soilbac.t)
soilbac.S
## T1_1 T1_2 T1_3 T7_1 T7_2 T7_3 DF_1 DF_2 CF_1 CF_2 CF_3</pre>
```

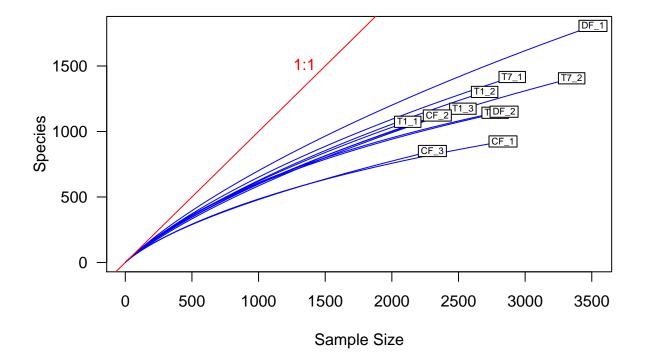

458

```
min.N <- min(rowSums(soilbac.t))
min.N</pre>
```

```
## [1] 2119
```

```
S.rarefy <- rarefy(x = soilbac.t, sample = min.N, se = TRUE)

rarecurve(x = soilbac.t, step = 20, col = "blue", cex = 0.6, las = 1)
abline(0, 1, col = 'red')
text(1500, 1500, "1:1", pos = 2, col = 'red')</pre>
```

4) SPECIES EVENNESS

Here, we consider how abundance varies among species, that is, **species evenness**.

Visualizing evenness: the rank abundance curve (RAC)

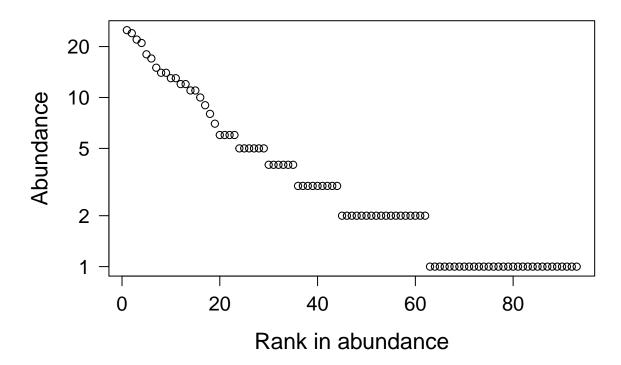

One of the most common ways to visualize evenness is in a **rank-abundance curve** (sometime referred to as a rank-abundance distribution or Whittaker plot). An RAC can be constructed by ranking species from the most abundant to the least abundant without respect to species labels (and hence no worries about 'ties' in abundance).

- 1. Write a function to construct a RAC,
- 2. Be sure your function removes species that have zero abundances,
- 3. Order the vector (RAC) from greatest (most abundant) to least (least abundant), and
- 4. Return the ranked vector

```
RAC <- function(x = ""){
    x = as.vector(x)
    x.ab = x[x > 0]
    x.ab.ranked = x.ab[order(x.ab, decreasing = TRUE)]
    return(x.ab.ranked)
}
```

Now, let's examine the RAC for site1 of the BCI data set.

- 1. Create a sequence of ranks and plot the RAC with natural-log-transformed abundances,
- 2. Label the x-axis "Rank in abundance" and the y-axis "log(abundance)"

Question 5: What effect does visualizing species abundance data on a log-scaled axis have on how we interpret evenness in the RAC?

Answer 5: The larger values don't seem as large as they really are compared to the smaller values, based on distance between ticks on y axis. This allows for a greater range of values to be displayed in a smaller area, but can be mis-leading if one does not pay attention to the scale (in which case abundance #s might seem more similar than they really are).

Now that we have visualized unevennes, it is time to quantify it using Simpson's evenness $(E_{1/D})$ and Smith and Wilson's evenness index (E_{var}) .

Simpson's evenness $(E_{1/D})$

- 1. Write the function to calculate $E_{1/D}$, and
- 2. Calculate $E_{1/D}$ for site1.

```
SimpE <- function(x = ""){
  S <- S.obs(x)
  x = as.data.frame(x)
  D <- diversity(x, "inv")
  E <- (D)/S
  return(E)</pre>
```

```
SimpE(site1)
##     1
## 0.4238232
```

Smith and Wilson's evenness index (E_{var})

In the R code chunk below, please do the following:

- 1. Write the function to calculate E_{var} ,
- 2. Calculate E_{var} for site1, and
- 3. Compare $E_{1/D}$ and E_{var} .

```
Evar <- function(x){
  x <- as.vector(x[x > 0])
  1 - (2/pi)*atan(var(log(x)))
}
Evar(site1)
```

```
## [1] 0.5067211
```

Question 6: Compare estimates of evenness for site1 of BCI using $E_{1/D}$ and E_{var} . Do they agree? If so, why? If not, why? What can you infer from the results.

Answer 6: The results from Simpson's Index compared to Smith and Wilson's Index are similar (0.42 vs 0.51, respectively). They are slightly different because the Simpson's Index gave more weight to abundant species, which I assume resulted in less evenness. Smith and Wilson's Index provided a less biased estimate of eveness.

5) INTEGRATING RICHNESS AND EVENNESS: DIVERSITY METRICS

So far, we have introduced two primary aspects of diversity, i.e., richness and evenness. Here, we will use popular indices to estimate diversity, which explicitly incorporate richness and evenness We will write our own diversity functions and compare them against the functions in vegan.

Shannon's diversity (a.k.a., Shannon's entropy)

- 1. Provide the code for calculating H' (Shannon's diversity),
- 2. Compare this estimate with the output of vegan's diversity function using method = "shannon".

```
ShanH <- function(x = ""){
    H = 0
    for (n_i in x) {
        if(n_i > 0) {
            p = n_i / sum(x)
            H = H - p*log(p)
        }
    }
    return(H)
}
```

[1] 4.018412

```
diversity(site1, index = "shannon")
```

[1] 4.018412

Simpson's diversity (or dominance)

In the R code chunk below, please do the following:

- 1. Provide the code for calculating D (Simpson's diversity),
- 2. Calculate both the inverse (1/D) and 1 D,
- 3. Compare this estimate with the output of vegan's diversity function using method = "simp".

```
SimpD <- function(x = "") {
    D = 0
    N = sum(x)
    for (n_i in x){
        D = D + (n_i^2)/(N^2)
    }
    return(D)
}

D.inv <- 1/SimpD(site1)
D.sub <- 1-SimpD(site1)
D.inv</pre>
```

[1] 39.41555

D. sub

[1] 0.9746293

```
diversity(site1, "inv")
## [1] 39.41555
diversity(site1, "simp")
```

[1] 0.9746293

Question 7: Compare estimates of evenness for site1 of BCI using $E_{H'}$ and E_{var} . Do they agree? If so, why? If not, why? What can you infer from the results.

Answer 7: Smith and Wilson's Evenness Index (Evar) output an evenness of 0.5 for site 1 of BCI, and the Shannon Index (H') output a value of 4.0. H' is measuring diversity by incorporating evenness and richness, while Evar is measuring evenness. Both #s seem to suggest that there is a moderate amount of diversity at the site, but don't seem to be directly comparable because they measure different things.

Fisher's α

In the R code chunk below, please do the following:

- 1. Provide the code for calculating Fisher's α ,
- 2. Calculate Fisher's α for site1 of BCI.

```
rac <- as.vector(site1[site1 > 0])
invD <- diversity(rac, "inv")
invD</pre>
```

[1] 39.41555

```
Fisher <- fisher.alpha(rac)
Fisher
```

[1] 35.67297

Question 8: How is Fisher's α different from $E_{H'}$ and E_{var} ? What does Fisher's α take into account that $E_{H'}$ and E_{var} do not?

Answer 8: Fisher's metric is different than Evar and H' because using Fisher's metric, diversity is estimated rather than just creating a diversity metric. Fisher's metric accounts for sampling error.

6) MOVING BEYOND UNIVARIATE METRICS OF α DIVERSITY

The diversity metrics that we just learned about attempt to integrate richness and evenness into a single, univariate metric. Although useful, information is invariably lost in this process. If we go back to the rank-abundance curve, we can retrieve additional information – and in some cases – make inferences about the processes influencing the structure of an ecological system.

Species abundance models

The RAC is a simple data structure that is both a vector of abundances. It is also a row in the site-by-species matrix (minus the zeros, i.e., absences).

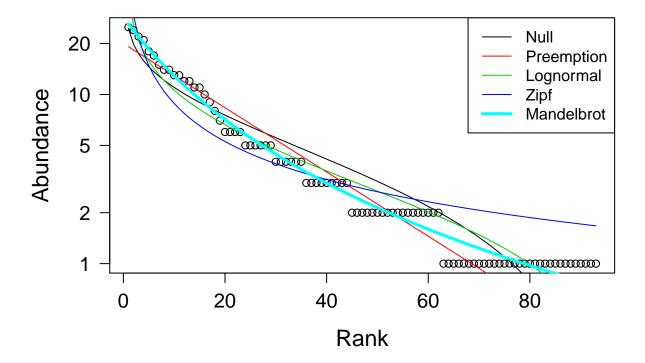

Predicting the form of the RAC is the first test that any biodiversity theory must pass and there are no less than 20 models that have attempted to explain the uneven form of the RAC across ecological systems.

- 1. Use the radfit() function in the vegan package to fit the predictions of various species abundance models to the RAC of site1 in BCI,
- 2. Display the results of the radfit() function, and
- 3. Plot the results of the radfit() function using the code provided in the handout.

```
RACresults <- radfit(site1)
RACresults
```

```

plot(RACresults, las = 1, cex.lab = 1.4, cex.axis = 1.25)
```

Question 9: Answer the following questions about the rank abundance curves: a) Based on the output of radfit() and plotting above, discuss which model best fits our rank-abundance curve for site1? b) Can we make any inferences about the forces, processes, and/or mechanisms influencing the structure of our system, e.g., an ecological community?

Answer 9a: The Mandelbrot model best fits our data, given that the AIC and BIC values are lowest, and that the line on the plot best tracks the data points. **Answer 9b**: It seems that in the system being analyzed, and many others, there are conditions that allow for a small # of species to be more abundant and a larger # species to be less abundant, which may be due to the predomination of a particular habitat type and niche partitioning amongst available habitats.

Question 10: Answer the following questions about the preemption model: a. What does the preemption model assume about the relationship between total abundance (N) and total resources that can be preempted? b. Why does the niche preemption model look like a straight line in the RAD plot?

Answer 10a: The preemption model assumes that species that are less abundant have less resources available to them. When there are more species present, there are less resources available for others. Answer 10b: The model assumes a constant decay in abundance of species when going from most the abundant species to the least abundant species.

Question 11: Why is it important to account for the number of parameters a model uses when judging how well it explains a given set of data?

Answer 11: Overfitting results when a model with many parameters is able to describe very well what was sampled specifically, but becomes worse at describing the real world. Thus, a more simple model may be better representing the real world that one is interested in, rather than just the sampled data.

SYNTHESIS

1. As stated by Magurran (2004) the $D = \sum p_i^2$ derivation of Simpson's Diversity only applies to communities of infinite size. For anything but an infinitely large community, Simpson's Diversity index is calculated as $D = \sum \frac{n_i(n_i-1)}{N(N-1)}$. Assuming a finite community, calculate Simpson's D, 1 - D, and Simpson's inverse (i.e. 1/D) for site 1 of the BCI site-by-species matrix.

```
\begin{aligned} & SimpDFin <- \text{ function}(x = \text{```}) \text{ } \{ \text{ } D = 0 \text{ } N = \text{sum}(x) \text{ } \text{for } (\text{n\_i in } x) \{ \text{ } D = D + (\text{n\_i}(\textit{n\_i -1})) / (N(\text{N-2})) \text{ } \} \\ & P.inv2 <- 1 / SimpDFin(\text{site1}) \text{ } D.inv2 \\ & P.sub2 <- 1 - SimpDFin(\text{site1}) \text{ } D.sub2 \\ & P. - SimpDFin(\text{site1}) \text{ } D. \end{aligned}
```

2. Along with the rank-abundance curve (RAC), another way to visualize the distribution of abundance among species is with a histogram (a.k.a., frequency distribution) that shows the frequency of different abundance classes. For example, in a given sample, there may be 10 species represented by a single individual, 8 species with two individuals, 4 species with three individuals, and so on. In fact, the rank-abundance curve and the frequency distribution are the two most common ways to visualize the species-abundance distribution (SAD) and to test species abundance models and biodiversity theories. To address this homework question, use the R function hist() to plot the frequency distribution for site 1 of the BCI site-by-species matrix, and describe the general pattern you see.

hist(rac)

The histogram shows that the vast majority of species (60+) have abundances of less than 5, and the rest (about 20 total) have abundances of 5 or more.

3. We asked you to find a biodiversity dataset with your partner. This data could be one of your own or it could be something that you obtained from the literature.

Load that dataset.

Woolly <- read.csv("data/hf08501bird.csv", sep = ",", header = TRUE)

Woolly

How many sites are there?

There are 19 sites.

How many species are there in the entire site-by-species matrix?

There are 49 species.

Any other interesting observations based on what you learned this week?

Each site is categorized as being affected by hemlock woolly adelgid to a varying degree, e.g. high, medium, and low. It will be interesting to find out how bird diversity has been affected by the hemlock woolly adelgid.
